CANINE URATE UROLITHS
Two distinct diseases are associated with urate urolithiasis in dogs, hepatic portovascular anomalies and an inherited alteration of the urate transporter encoded by the SLC2A9 gene. Common to both is inefficient transport of serum uric acid into hepatocytes where uric acid is enzymatically degraded into the highly water-soluble end-product, allantoin.

PREVENTION

** Review manufacturer’s therapeutic food literature to determine indications/contraindications. For pets with multiple health concerns, consult a veterinary nutritionist to select an optimal food.

** In depth recommendations and references are available on our website: urolithcenter.org under the resources tab.
Minimizing Urate Urolith Recurrence

Medical considerations:
- A mutation in the urate transporter has been identified in Dalmatians, English Bulldogs, and Black Russian Terriers. Other breeds should be tested for hepatic porto-vascular anomalies. If bile acids are normal, consider genetic testing to identify possible hereditary defects in the urate transporter gene.2, 3
- Treatment of uroliths should complement, and not supersede appropriate management of liver disease.

Nutritional considerations:
- Feed diets with lower quantities of high-biological-value protein (i.e. lower protein is consistent with lower purine). Avoid diets containing organ meat (e.g. liver and kidney) as their primary protein source, and favor diets containing egg and whey (e.g. dairy, casein).
- Feed diets that promote diuresis, and excretion of alkaline urine.
- High moisture foods (i.e. canned formulations) are more effective because increased water consumption is associated with decreased urine concentrations of calculogenic minerals. Feed canned foods and/or add increasing amounts of water to food until specific gravity is less than 1.020.

Pharmacological considerations:
- If dietary therapy alone is ineffective, consider long-term therapy with allopurinol (5 to 7 mg/kg/day). Higher doses of allopurinol, especially when given with higher protein foods, increase the risk of xanthine urolith formation. Allopurinol may not be as effective in dogs with porto-vascular disease.
- Consider potassium citrate (75mg/kg, q 12-24hr) if urine pH is consistently less than 6.6.

Consider These Facts:
- In a cross-over study, feeding Dalmatians Prescription Diet® u/d® reduced urate urolith recurrence and urine urate concentration, and increased urine pH and volume.4
- Rice and eggs are excellent sources of low purine nutrition; and are the major ingredients of Prescription Diet® i/d® Sensitive Canine, Prescription Diet® l/d® Canine, and Prescription Diet® u/d® Canine.
- In a case series of 10 dogs with previous urate urolithiasis, allopurinol administration in excess of 9 to 38 mg/kg/day was associated with xanthine urolith formation. This occurs because allopurinol inhibits the breakdown of xanthine to uric acid, and because xanthine is less soluble in urine than uric acid. The dose of allopurinol to sufficiently prevent urate urolith recurrence without xanthine urolith formation is variable and influenced by the severity of disease, the quantity of protein (i.e. purines) in the diet, urine pH, and urine volume. Therefore, a reduction in dietary purine, should precede the prescription of allopurinol.5
- Urate uroliths are rare in female Dalmatians (3% of 9095 urate urolith forming Dalmatians). Therefore, urate prevention in female Dalmatians without a history of uroliths is probably not needed.5
**MINIMIZING CANINE AMMONIUM URATE UROLITH RECURRENCE**

**Therapy:**
- Correction of portovascular anomalies appears logical. However, further studies are needed to determine the efficacy of hepatic vascular restoration on urate urolith recurrence.
- Consider diets with reduced protein (and therefore reduced purines) that promote formation of urine with a pH ≥ 6.6 (e.g. Prescription Diets® u/d®, k/d®, l/d® Canine fit these criteria)

**Monitor:**
- Urinalysis in 1 month and then every 3 to 6 months
- Consider appropriate medical imaging (early stones are likely to be small and radiolucent, consider ultrasonography) every 6 months, or sooner in patients with recurrent urinary signs.

---

**Urine pH ≥ 6.6 & USG ≤ 1.020**
- These parameters are ideal for successful urate prevention

**Urine pH < 6.6**
- To verify, measure using pH meter
- With repeatable aciduria, consider diets with less acidic precursors or addition of potassium citrate
- Continue therapy and monitor every 3 to 6 months

**USG > 1.020**
- Encourage feeding only canned food.
- Alternatively, additional water can be added to any food formulation

**Urate Crystalluria**
- Verify persistent, in vivo crystalluria by reevaluating an appropriately collected (in hospital) fresh urine sample analyzed within 30 minutes.
- Urate crystals rapidly precipitate as urine cools.
- If persistent, consider allopurinol with appropriate diet therapy

**Uroliths**
- Consider minimally invasive techniques or surgery to remove recurrent uroliths.
- Submit retrieved uroliths for quantitative analysis
